

SPECIFYING WHAT PEOPLE UNDERSTAND WITH MSFA

Kow KURODA

National Institute of Communications Technology (NICT), Japan

11/28/2005

TODAY'S TOPIC

- Introducing *MSFA, Multi-layered Semantic Frame Analysis* (Kuroda and Isahara 2005)
 - (Briefly) comparing it with *Berkeley FrameNet (BFN)* (Fillmore, et al. 2003)
 - Presenting a sample MSFA of an English sentence
- With ONE IMPORTANT CAVEAT:
 - So far, MSFA has been done for Japanese sentences: just a few sample analyses were attempted for English.
 - Note that this is kind of inevitable, because MSFA requires, *by its very design*, an annotator / analyst to specify a lot of knowledge hard to access for non-native speakers.

OMITTED TOPIC

- MSFA is coupled with a theoretical framework called *FOCAL, Frame-Oriented Concept Analysis of Language* (Kuroda, et al. 2005; Nakamoto, et al. 2005).
- But we don't have enough time to talk about FOCAL today.

OUTLINE OF TALK

- Presenting sample MSFAs
 - Explain how MSFA goes
 - Explain how MSFA is related to “ontologies”
- Giving some background
 - Especially why I deviated from Berkeley FrameNet (Fillmore et al. 2003)
- Summary

HOW MSFA GOES
—SAMPLE ANALYSIS—

OVERVIEW OF MSFA

- MSFA is a BFN-inspired framework for *text analysis* by linguists such that
 - it combines linguistic analysis with text annotation for “deeper” semantics
 - it makes linguistic analysis “database-ready”
- MSFA’s goal is NOT just a development of a language resource *usable for NLP tasks only*.
 - I’m rather a researcher in Cognitive Science, rather than being a linguist, or an NLP guy.
 - Rather, it aims at a versatile resource that enhances as many researches as possible in Cognitive Science/Psychology, as well as tasks in NLP.

MSFA PROCEDURE (SIMPLIFIED)

1. Segment a sentences S into units U_1, \dots, U_n .
 - Note incidentally that it's better NOT to try to build up larger units from smaller units. This tends to lead annotators to a "false" analysis.
 - This is not independent from Step 2. So, you need to go cyclic.
2. For each U_i , find a set of frames F_1, \dots, F_m so that one of their "frame elements" is *realized* by U_i .
 - This is called "evocation" in the *Frame Semantics* literature.
3. Specify relationships among all the frames.
 1. Relevant relations are: " F elaborates G " (deals with Inheritance), " F constitutes G " (deals with part-of relations), " F presupposes G " (deals with "logical implications")

GUIDING PRINCIPLES

- “Be meticulous”
 - Every word (or morpheme if morphological analysis is necessary) needs to realize at least one semantic role, i.e., “frame element” of a frame.
 - You are not allowed to ignore a minor element by saying “its meaning is *uninteresting*.” If this “excuse” is allowed, your analysis will get arbitrary very soon.
- “Be greedy”
 - To every word, you need to assign as many semantic roles as possible if they are not incompatible
 - It is an open question how many frames you need specify: there is no a priori way to tell when an MSFA is “done.”

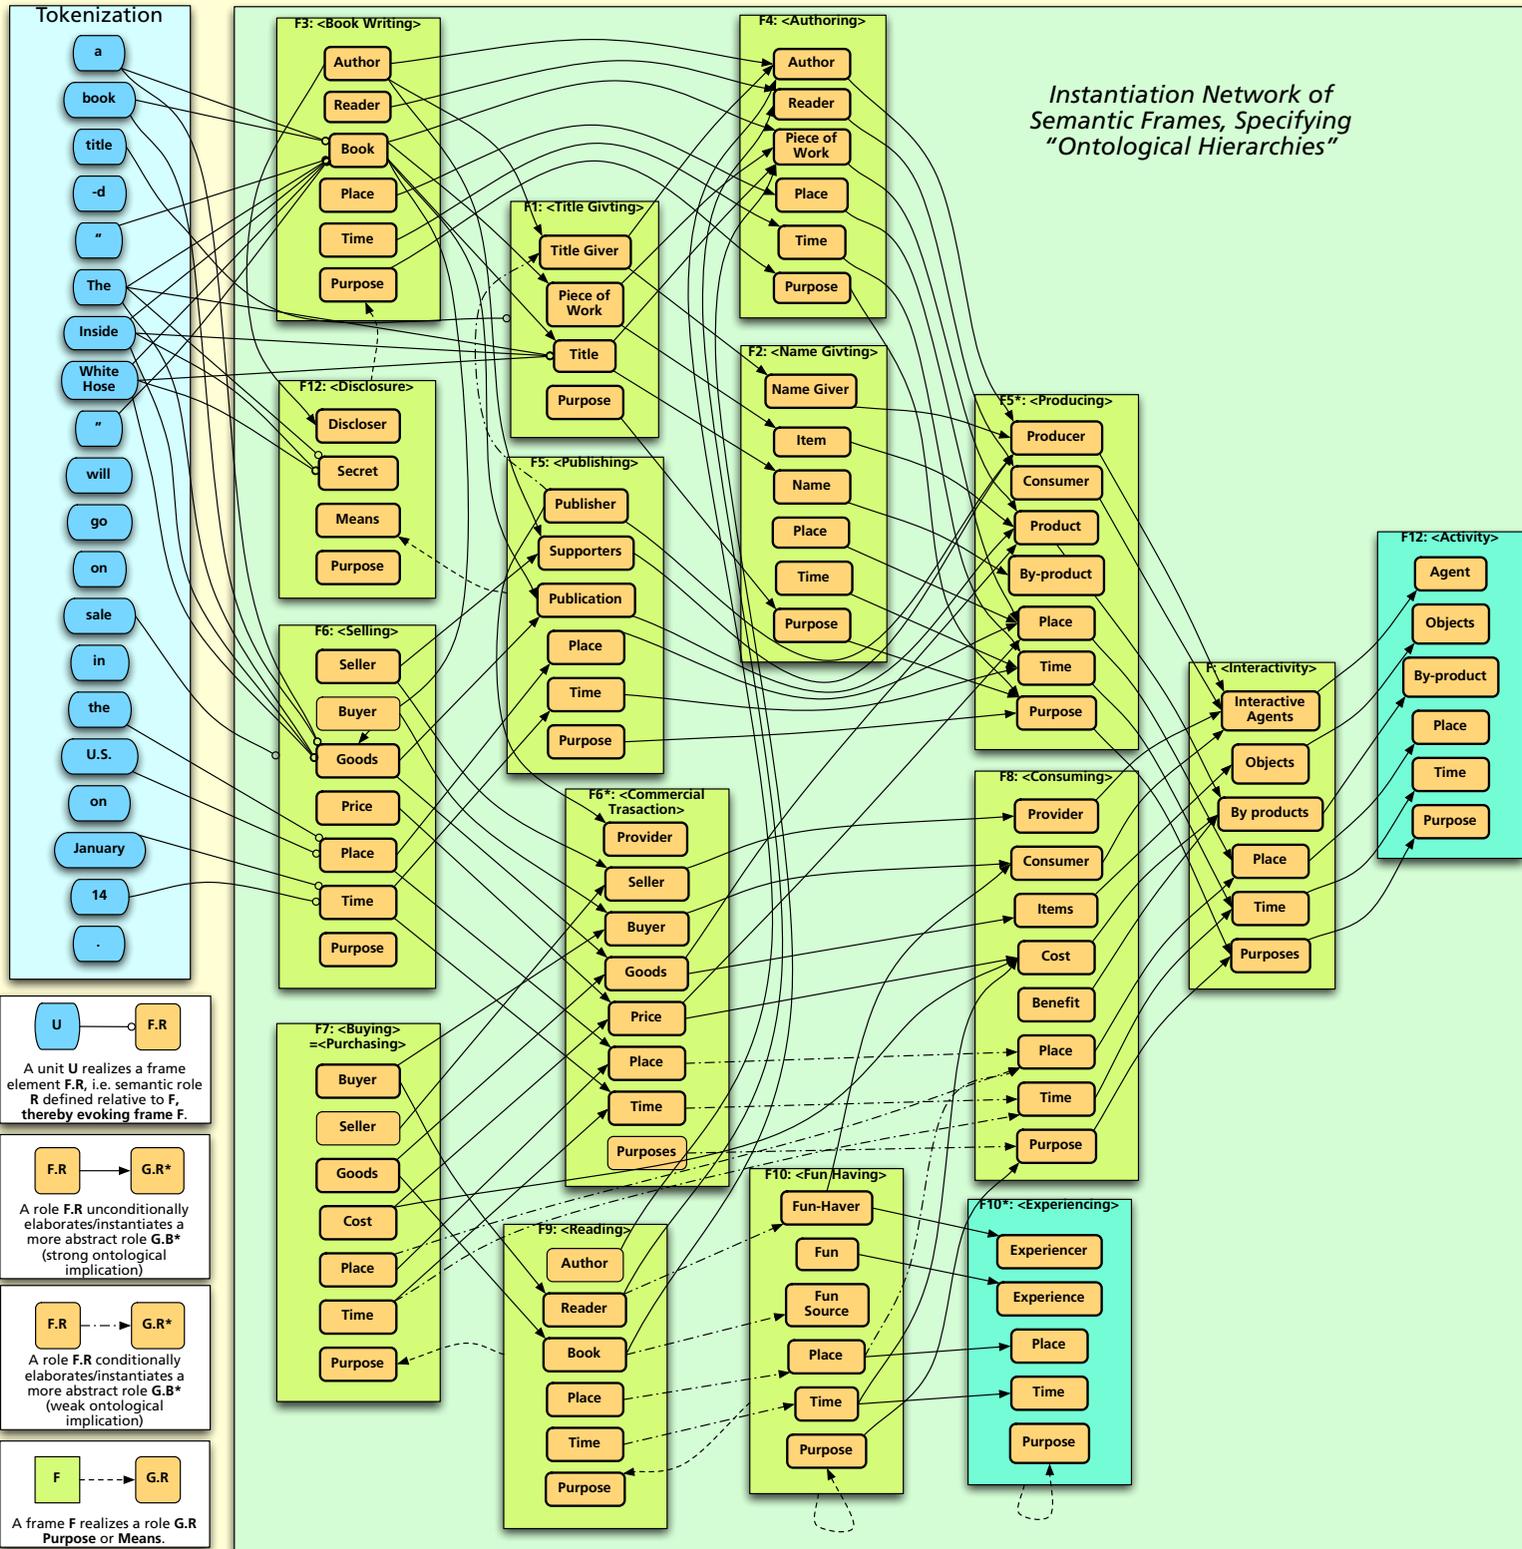

SAMPLE MSFA

- An English translation of a Japanese Newspaper article taken from *Kyodai Corpus* (Kurohashi and Nagao 1994):
 1. *A book titled “Inside the White House” will go on sale in the U.S. on January 14.*
 2. *The book will definitely be a much-talked-about, severely criticizing the past U.S. Presidents and their aides.*
 3. *The title came as latest work of Ronald Kesler, an expert reporter and investigator at the “Washington Post” and other media.*
 4. *The book, for instance, reveals the following episodes.*
 5. ...

SAMPLE MSFA

- The following is the original Japanese text:
 1. 「ホワイトハウスの内側」という本が十四日、米国で発売される。
 2. 歴代大統領と関係者をこきおろしており、話題になるのは間違いない。
 3. 「ワシントン・ポスト」紙などで長年、調査報道をしてきたロナルド・ケストラー氏の新著。
 4. 例えば次のような内容だ。
 5. ...

Instantiation Network of Semantic Frames, Specifying "Ontological Hierarchies"

HIERARCHY OF FRAMES AND FRAME ELEMENTS

- The hierarchy of frames, especially the hierarchy of frame elements, expresses conceptual hierarchies you usually find in thesauri, e.g., *WordNet* synset hierarchies.
- Why?
- A possible —and very reasonable— answer is
 - Instantiation links express “ontological hierarchies,”
 - Part —and a probably substantial body— of human conceptual system is an organization of semantic “roles” rather than one of semantic “types”

FRAMES AND FRAME ELEMENTS

- What MSFA is meant to do is to *list up all the relevant situations* in text understanding in terms of frames, assuming that:
 - Frames are organizations of frame elements, i.e., situation-specific “semantic roles”
 - *Author*, as a concept, names an Agent-class semantic role specific to the “Authoring” situation.
 - *Writer*, as a concept, names an Agent-class semantic role specific to the “Writing” situation, a subclass of “Authoring.”
 - Frames are organized in principled ways.
 - So-called “thematic roles”, or “deep cases” are most abstract semantic roles.

WSD NEEDS TO BE FRAME-WISE

- “Entities” in the understood content of a text may—and tend to—*realize multiple roles/frame elements simultaneously*.
 - For example, *book* realizes such roles as:
 - <Information Carrier> in <Reading> frame
 - <Good> in <Selling/Buying> frame
 - <Piece of Work> in <Writing> frame
 - <Publication> in <Publishing> frame
- This means that *Word Sense Disambiguation (WSD)* *needs to be done frame-wise*, explaining why WSD isn't enough for text understanding, at least for *simplex* one.

CURRENT STATUS

- MSFA was done to a tiny portion of *Kyodai Corpus* texts (3 articles, 63 sentences)
 - *Kyodai Corpus* is a collection of Japanese newspaper articles: its English translation is complete at NICT.
- Characteristics
 - No full evaluation yet
 - We need feedback from limited users, but publication is not unrestricted.
 - But, on average, a sentence has nearly 60 frames, showing that MSFA provides much deeper, ontology-based semantics than BFN.

REALLY NEED A FRAME DATABASE?

- Unlike BFN, frames are identified and defined in an *ad hoc* manner, which is a method based on a deliberate decision.
 - MSFA does NOT make wide-coverage a priority.
 - Basically, the way MSFA works is *exploratory*, and it MAY not assume a pre-existing database of frames.
 - So, we *may* be faced with the “standardization” issue.
- Why? — Nobody knows the *optimal* granularity in semantic description even in terms of frames.
 - This means that a large-scale development of a frame database *can* be premature (but who knows?)

MSFA AND BFN ANALYSIS

- In principle, frames used in MSFA are defined independently of BFN frames.
 - We DO NOT assume that BFN frames for (U.S.) English are applicable to Japanese without modification.
 - Kanamaru, et al. (2005) examined the correspondence between the MSFA and BFN frames, showing that BFN frames are coarse-grained than MSFA frames.
 - To get a more precise assessment for compatibility, we expect much to text annotation in *Japanese FrameNet* (Ohara, et al. 2003, 2004), but nothing has come out (yet).
 - It's vital to know how it will look like when BFN frames are applied to the analysis of Japanese texts.

WHY MSFA, NOT BFN?
—A BACKGROUND—

BEYOND WSD

- Text understanding is NOT simply a task of *Word Sense Disambiguation* (WSD). Clearly, a lot more is needed.
 - (Too) many researchers in NLP, and even in Linguistics and Psychology, believe that semantic analysis reduces to the WSD problem.
- The real question is,
 - What is WSD needed *for*?
 - *Exactly what else* is needed in addition to WSD?
- To this question, *Frame Semantics* (Fillmore 1985; Fillmore and Atkins 1994) comes to rescue.

GETTING OUT OF A "VICIOUS CIRCLE"

- MSFA is a derivative of *Frame Semantics (FS)*, addressing the following two questions:
- For a given sentence S ,
 - A. How to specify *what people understand* when they hear or read S ? — Call this the "Specification" Problem
 - B. How to represent *what people understand* when they hear or read S ? — Call this the "Representation" Problem
- MSFA is NOT concerned with the "truth" of S .
 - As FS says, knowing "what to do with S " is crucial. Knowing "when an S is true" is subsidiary.

GETTING OUT OF A "VICIOUS CIRCLE"

- The "Representation" Problem makes sense only when the "Specification" Problem is properly treated.
- But, the question is, *Is the "Specification" Problem properly treated?*
- The answer is, *No*, obviously.
- But why? — Linguists, at least in the Post-Chomskian linguistics, are in a "vicious circle."

BEFORE YOU TRY TO EXPLAIN ANYTHING ...

- Why?
 - Linguists have always tried to “explain” why people interpret such and such things, in such and such ways, without meeting the “Specification” Problem.
 - So, Linguistics is too immature a science even now: virtually *any* explanation in linguistics is arbitrary.
- So what?
 - We need to specify what people understands in sentences *before explaining why people do so.*
 - Linguists, too, need to be checked if their “interpretations” are the same as the real hearer/reader’s performances in some way.
 - FOCAL provides such opportunities.

BUT WHY DEVIATE FROM BFN?

- Important fact:
 - There is no guarantee that frames provided by BFN have an optimal semantic granularity.
- This means that you need to check the *psychological reality* of descriptive devices, i.e., frames, used to specify the meaning of sentences.
 - You can't trust on linguists too much, as you already know.
 - If you are too candid to believe BFN frames as such, your analysis will soon get arbitrary.

TEST CASE: "ATTACK" FRAME

- (Some of) BFN frames can't account for some cases of selectional restrictions: For example, <Attack> frame with core FEs <Assailant> and <Victim> can't fully explain the following patterns:
 1. The lion attacked {a. the flock of impalas; b. ???the bank branch; c. ??innocent people on street}
 2. The robbers attacked {a. ???the flock of impalas; b. the bank branch; c. ?innocent people on street}.
 3. The random killer attacked {a. ???the flock of impalas; b. ?? the bank branch; c. innocent people on street}.
- More granularity, which differentiates the <Purpose> of an <Assailant>, is clearly needed to account for this sort of selectional restrictions.

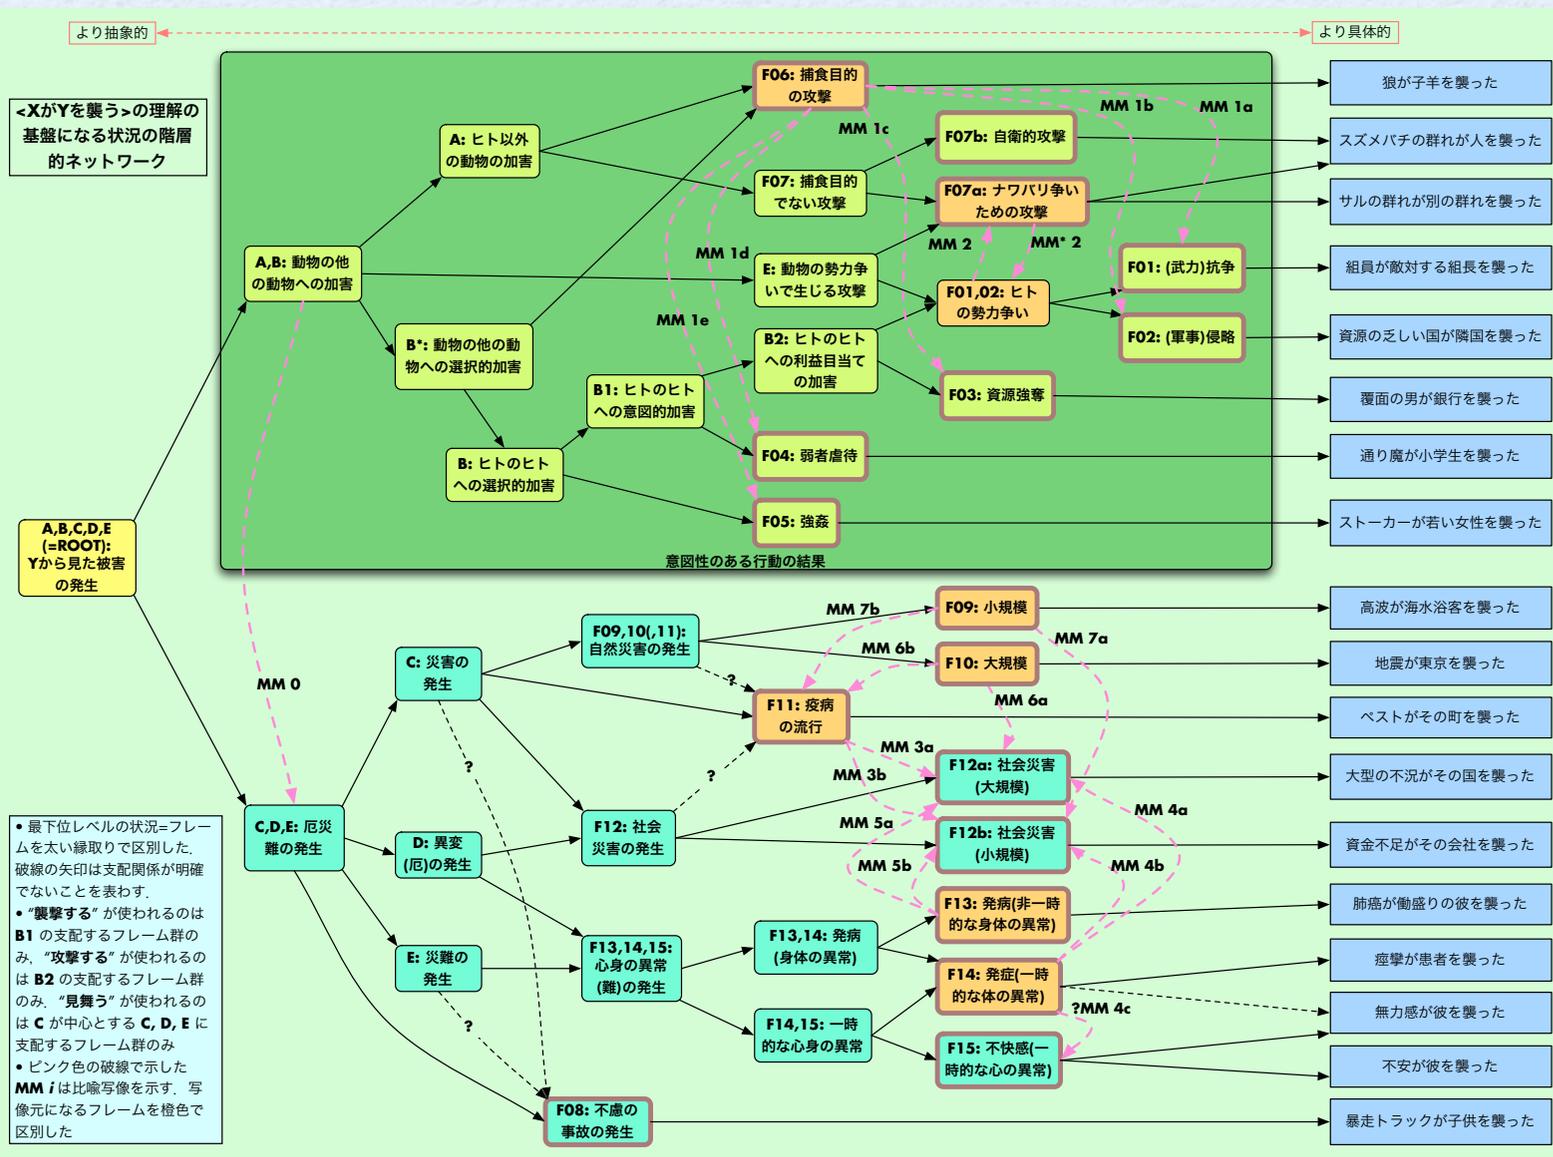

DESIDERATA

- The optimality of semantic analysis / annotation in terms of *granularity* is task-dependent.
 - There is NO optimal level for semantic analysis without specifying what you want to do with it.
- The best way is
 - NOT to disguise yourself as defining semantic frames at the optimal level of granularity.
 - to assign a granularity index to each frame, ranging from a shallow to a very deep level one.

WHY FINER GRANULARITY?

- Given a frame for a verb XVY (e.g., X attack Y), you have a set of *semantic co-variations* between X and Y in terms of finer-grained semantic types.
 - Selectional restrictions clearly correlate with units of such co-variations. For example, a <Predator> only attacks a <Prey> living in the same environment. This explains why the following contrasts:
 - The {a. tuna; b. ???wolf} attacked the sardins.
 - The {a. ???tuna; b. wolf} attacked the sheep.
- Usually, BFN frames have a number of subclasses, which serves as “units” of selectional restrictions.

FOCAL ON RESCUE?

For the case of “X-ga Y-wo osou” (“X attacks Y”, “X hits Y” in English), 15 different situations F01, F02, ... , F15, were identified by FOCAL and were shown to make sense to non-linguists through experiments.

SUMMARY

- MSFA tries to overcome some weaknesses of BFN by providing much finer-grained semantic analysis than BFN, to fully account for most cases of selectional restrictions.
- MSFA is not as useful as BFN for NLP: it doesn't try to provide a wide-coverage database of frames.
- My tentative evaluation:
 - MSFA would be more preferable for researches in Cognitive Science/Psychology than linguistic resource developments in NLP.
 - But NLP will require semantic descriptions at this level of finer-granularity sooner or later.

ACKNOWLEDGEMENTS
